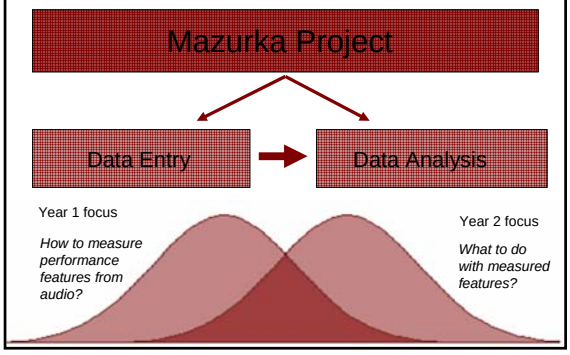
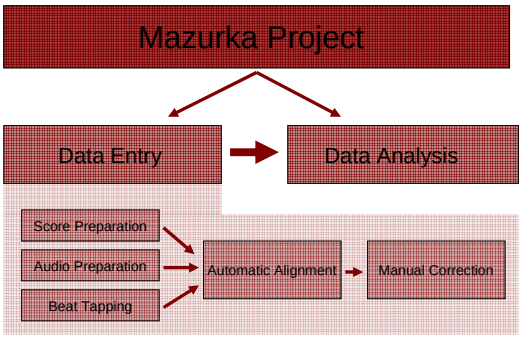
6. Performance Simulations
7. Initial Analysis

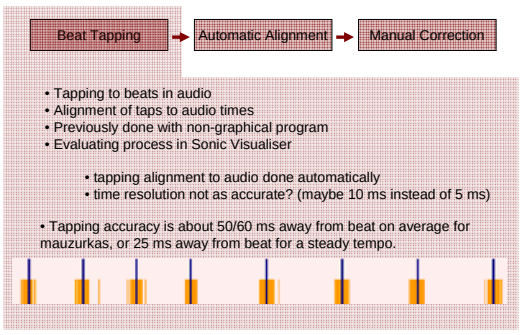
Top-Down Overview



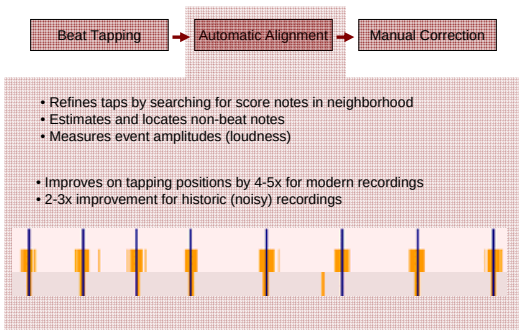
Top-Down Overview



Data Entry Process



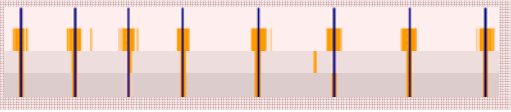
Data Entry Process



Data Entry Process

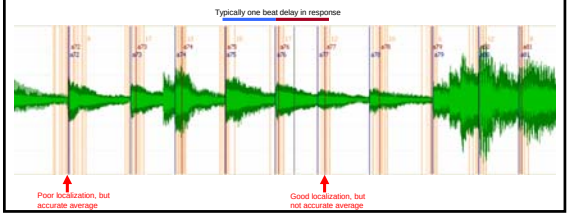
Beat Tapping → Automatic Alignment → Manual Correction

- Fix obvious errors in automatic alignment
- Verify automatic alignment by listening to clicks and music simultaneously



Reverse Conducting

- Orange = individual taps (multiple sessions) which create bands of time about 100 ms wide.
- Red = average time of individual taps for a particular beat
- Blue = actual beat onset times



Power Measurements (for manual corrections)

MzPowerCurve

- *Sonic Visualiser plugin to do various power measurements*

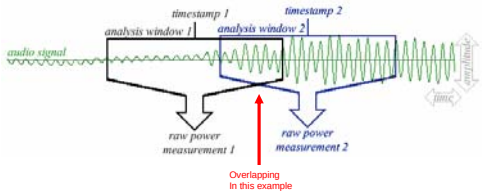
  http://sv.mazurka.org.uk/MzPowerCurve

- #1 raw power measurements – average and weighted

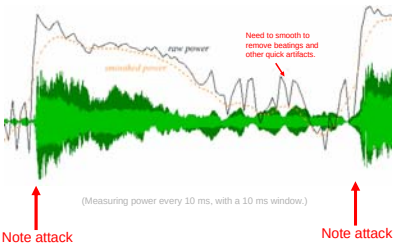
$$P_{avg} = 10\log_{10}\left(\frac{1}{N}\sum_n x_n^2\right) \qquad P_{wavg} = 10\log_{10}\left(\frac{1}{N}\sum_n x_n^2 w_n\right)$$

- #2 smoothed power – useful for basic dynamics measurements
- #3,4 smoothed power slope – useful for manual corrections of note attacks (for percussive instruments such as piano).

Window and Hop



Raw and Smoothed power



- Smoothed power useful for getting basic dynamics levels.

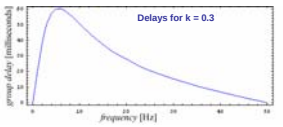
Smoothing Filter

• Using a filter called an *exponential smoother*:

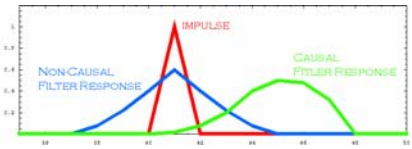
$$y[n] = k\ x[n] + (1-k)\ y[n-1]$$

Englishish: The current output equals the current input times the value *k*, plus the previous output times the value 1-*k*.

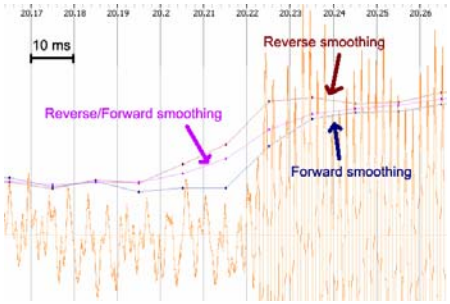
• All filters delay the input. Since this filter feeds back on itself, the filter will delay some frequencies more than others:



Symmetric Filtering



Filtering Direction



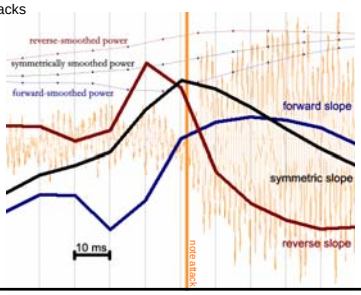
Smoothing Direction

• Avoid the funny delays by symmetric filtering

• Then slope of smoothed power aligns nicely with percussive note attacks

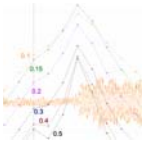
• symmetric filtering is best for localizing attacks

• reverse filtering is best for dynamics estimation

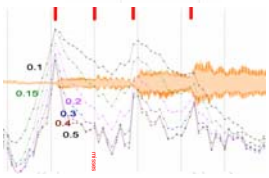


Smoothed Power Slope

Attack on measurements

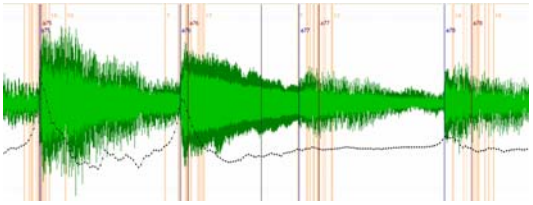


Attack ½ between measurements



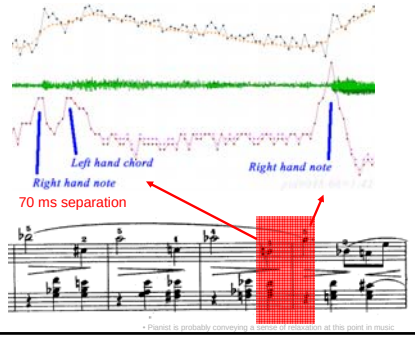
• smoothing factor of about 0.2 gives best results over a variety of conditions

Power Slope for Correcting



Not helpful for this beat (no peak)

Non-Synchronous Hands



• > 30 ms separation may be significant

Advantages/Disadvantages

• Time domain analysis, so localization can be better than for frequency analysis metrics (E.g. Earis & Bello methods)

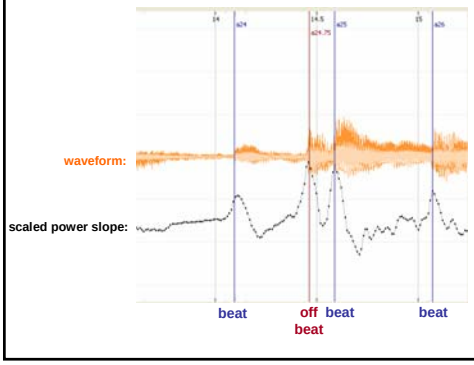
• Ignores frequency content, so not always or accurate.

•Good for instruments with percussive attacks (i.e. piano, drums)

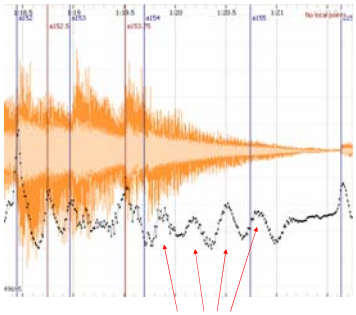
• Probably not good for non-percussive instruments: voice, violin, woodwinds, brass, etc.

Manual Correction

Beats + Offbeats

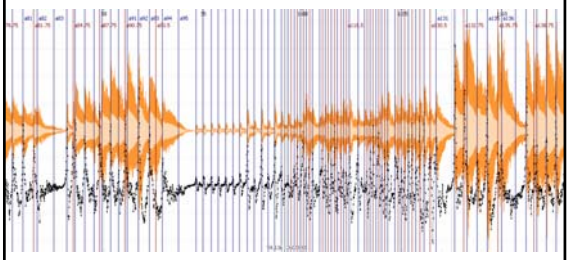


Advantage of Having the Score



• If you don't have a score, you are wasting your time.

Large-scale View of Beats/Offbeats



• Layer clicks can be played with different timbres/loudness.

Probable Entry Scenario

0. Become familiar with the performance. (Score already entered) (15 min)
- Tap to performance in Sonic Visualiser (5 min)
- Cursory check of beat positions with onset annotations (10 min)
- Interpolate off-beat positions based on score
- View/listen to audio with beats/off-beats and automatic annotations (10 min)
- Automatic adjustments of the onset times of beats/off-beats
- Careful manual proof listening/reading of the automatically adjusted times (30 min)
- Extract secondary performance features such as dynamics and non-simultaneous chord notes.

red: manual time estimates for a 5 minute piece

→ about 2 hours for 5 minutes of music

Automatic Alignment Evaluation

Summary

• Automatic alignment improves accuracy about 4-5x for modern recordings and 2-3x for historic recordings when compared to reverse conducting accuracy.

• **Earis system parameter search optimization**

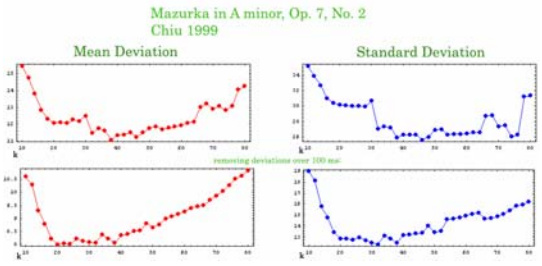
1. wavenumber (k)
2. low-pass filter order (LPF)
3. tuning factor

• **Other evaluation/exploration for the system:**

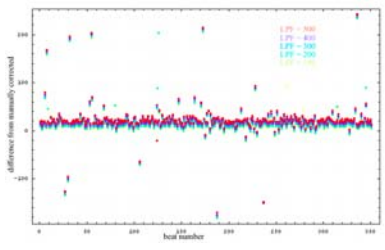
1. search window method
2. square/Gaussian window method
3. recursive processing
4. wanderer identification
5. removing harmonics of previous event
6. symmetric LPF filtering

k Parameter Sensitivity

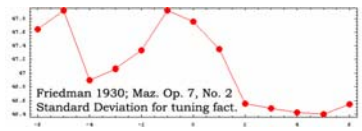
k = wave number (how many cycles of a sinewave) to analyze with

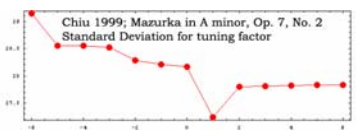


LPF Parameter

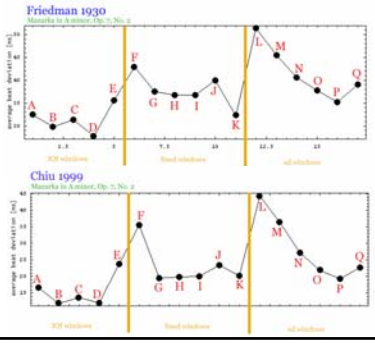


Tuning parameter





Windowing Methods



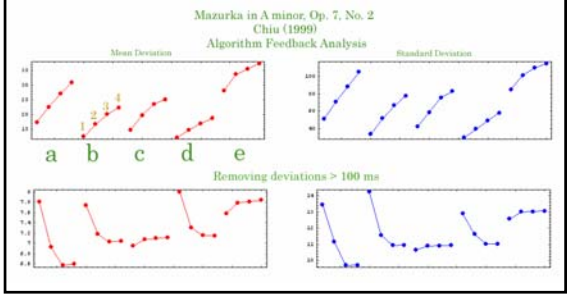
a = [-0.33 ioi : 0.33 ioi]
b = [-0.50 ioi : 0.50 ioi]
c = [-0.67 ioi : 0.67 ioi]
d = [-0.33 ioi : 0.67 ioi]
e = [-1.00 ioi : 0.67 ioi]
f = [-100 ms : 100 ms]
g = [-200 ms : 200 ms]
h = [-300 ms : 300 ms]
i = [-400 ms : 400 ms]
j = [-500 ms : 500 ms]
k = [-200 ms : 500 ms]
l = [-1 sd : 1 sd]
m = [-2 sd : 2 sd]
n = [-3 sd : 3 sd]
o = [-4 sd : 4 sd]
p = [-5 sd : 5 sd]
q = [-2 sd : 4 sd]

• IOI is best method

Hybrid Window Shape

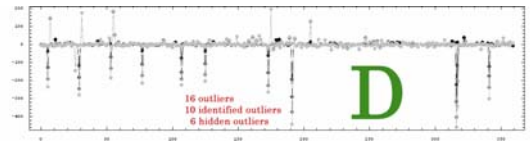
	all beats	good beats
Chiu 1999:	100%	60%
Friedman 1930:	75%	50%

Recursion effect on localization

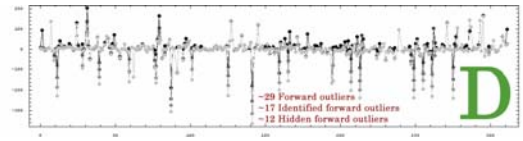


Recursion & Wandering

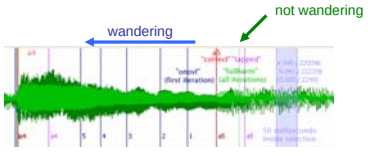
modern recording



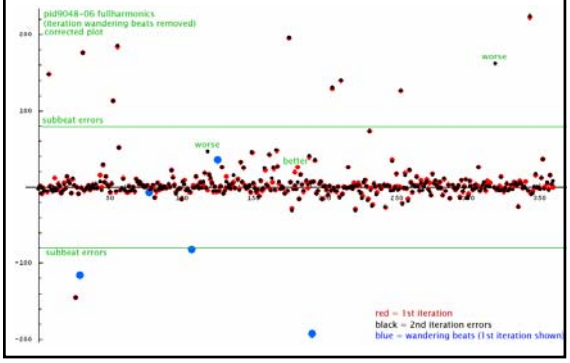
historic recording



Wandering



Wanderers



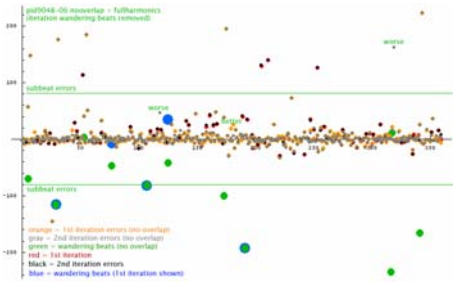
Wanderers (2)

• events which the analysis method cannot "see".

Wandering (3)

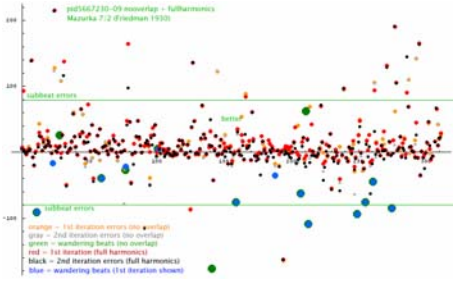
Selective Harmonics

• Remove shared harmonics with previous event to improve attack identification and remove potentially beating harmonics.



• Removing shared harmonics with previous events didn't help: more wanderers.

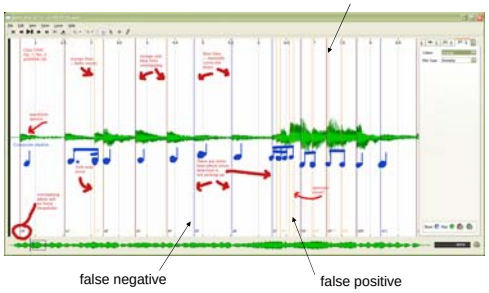
Selective Harmonics (2)



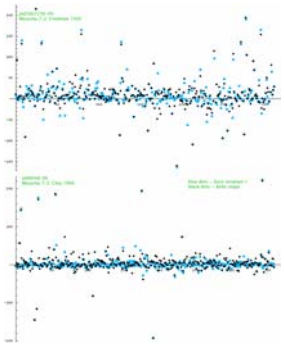
Bello Onsets

http://mazurka.org.uk/auto/onset

• Spectral measurements used to identify event onset locations
• Can give false positivies and false negatives
• Does not utilize a score



Onset Snapping

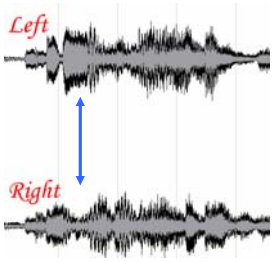


• Snap earis to bello if a bello onset is less than 50 ms away.

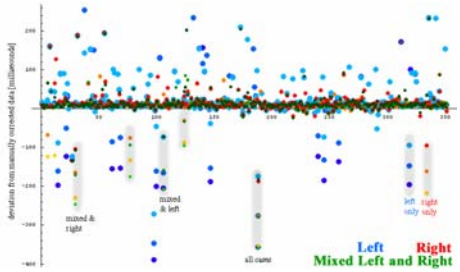
Friedman 1930, Mazurka 7/2:
iteration 1 mean deviation: 22.0 ms
bello snapping md: 22.1 ms

Chiu 1999, Mazurka 7/2:
iteration 1 mean deviation: 10.5 ms
bello snapping md: 13.4 ms

Stereo Differences

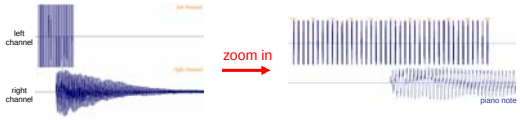


Stereo Comparison

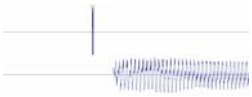


Experiments

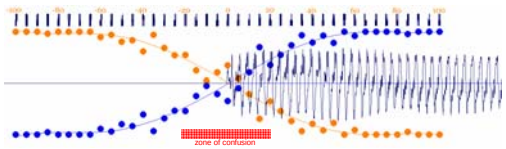
Note Onset Time Resolution



• Play one of these clicks and ask listener: did it come before or after the start of the piano note?



Note Onset Time Resolution

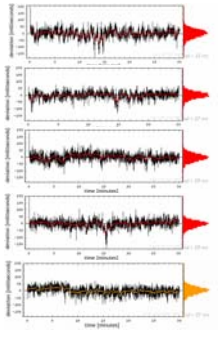


• 75% accuracy or better outside -21.2 to +22.0 ms range around note attack.

• Symmetric about the note onset.

• Very accurate to distinguish which came first when difference is > 60 ms.

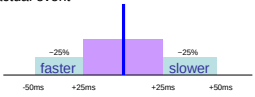
Tapping Accuracy



• Tap for 30 minutes to a constant tempo

• 50% of taps occur within +/- 25 ms of actual event

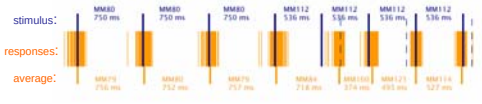
• 95% of taps occur within +/- 50 ms of actual event



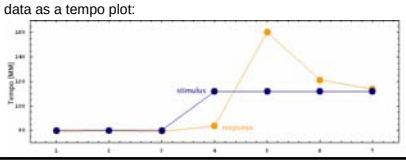
• For Mazurkas (significant tempo changes), accuracy is about twice as much (50% occur within 50 ms of actual event).

Unpredictable Tempo Changes

- **Tapping to an unknown sudden change in tempo**
- Suddenly faster:



Same data as a tempo plot:



Unpredictable Tempo Changes (2)

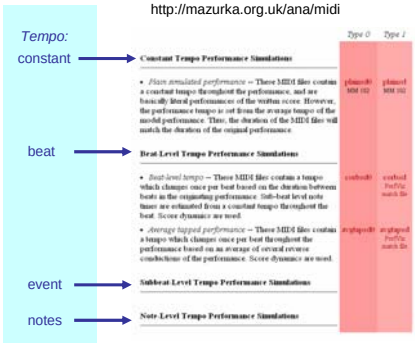
Performance Simulations

Performance Feature Layers

http://mazurka.org.uk/ana/midi



Performance Components

Tempo/Timing

1. Average tempo (of entire piece)
2. Beat-to-beat tempo
3. Sub-beat timings (continuous tempo)
4. Non-simultaneous events (LH/RH, arpgggios)

Dynamics

1. Score dynamics
2. Composite loudness
3. LH/RH loudness
4. Individual note loudness

PerfViz

• 3D performance worm visualiser by Martin Gasser (Vienna)
